

For example: If no list instance has been created, write statements in the main program to create a mylist instance with ordered inputs 1, 2, 3, 4, and 5. Ensure the resulting output is 1, 2, 3, 4, 5 by using the LinkedList class methods we have learned.

First of all, I suggest you to use pencil or pen to underline or circle the **important parts of Question**, ask yourself,

1. What is the question want to do?
2. What are inputs and what are outputs?

The wrong solution is:

```
mylist = LinkedList()  
mylist.add(1)  
mylist.add(2)  
mylist.add(3)  
mylist.add(4)  
mylist.add(5)
```

Why is it wrong?

The right solution is:

For example: If an instance of mylist already exists containing the value 3, write statements in main program to create the instance variable mylist with ordered inputs are 1, 2, 4, 5 and has result outputs are 1, 2, 3, 4, 5 by using class LinkedList's methods that we learned.

The solution is:

mylist = LinkedList() **×** no need to create a new instance variable

mylist.add(1)

mylist.add(2) **×** not use add method
